Corpora in Translation: A Slovene Perspective

Špela Vintar

spela.vintar@guest.arnes.si

1. Introduction

A few decades ago, the stereotypical image of a translator would most likely be one of an overworked, slightly grey female or balding male nailed to a desk under a heap of dictionaries and encyclopaedias, leading a rather solitary life. Today, a more realistic picture of a translator at work would inevitably feature a computer with an internet browser minimised on the task bar and the heap of dictionaries similarly replaced by an array of desktop icons.

It is a fact, yet to be acknowledged by many practising translators and translation scholars, that the digital age brought to the translation business a revolution much more profound than merely switching from paper to the computer screen. The abundance of electronic texts on the web, available in most languages of the world and often multilingual, is just one of the reasons that paper dictionaries – nor electronic editions of these same reference works for that matter - can no longer be considered the primary source of translation-relevant information. Another reason, closely related to the main credo of corpus linguistics that the primary element of analysis in language is the text, is that translators extremely rarely translate words in isolation. Any reference work that presents words devoid of textual context is thus of limited value in a translation environment.

If in the early years of corpus linguistics electronic text collections were still considered a luxury for various reasons, among them the cost of computer storage and the complexity of processing large amounts of textual data, in the past decade the situation has changed radically. Indeed, it now seems obsolete to even compile corpora; instead of fixed collections of texts we are entering an era of tools for dynamic corpus creation in accordance with specific and individual requirements.

Naturally, there are still arguments in favour of proper corpora versus ad hoc text collections created dynamically by trawling the Web. The difference between ‘real’ language, although no corpus could ever claim to truly represent it, and the language of the Web, may best be illustrated by comparing a page of concordances obtained from a site such as WebCorp (http://www.webcorp.org.uk/ [21.11.07]) with one from Wordbanks Online (formerly known as Bank of English; http://www.collins.co.uk/corpus/CorpusSearch.aspx [21.11.07]) or any other large monolingual corpus. It seems that certain language varieties, for example literary language, are virtually non-existent or seriously under-represented on the Internet, while others like commerce, computers or the informal chatty style of web forums claim a substantial part of bandwidth.
The availability of corpora did not go unnoticed by progressive translators. The most valuable corpus type, often designed explicitly for translators, is of course the parallel corpus, giving each language segment in two or more languages. By offering translations of segments instead of equivalents of words, a parallel corpus shifts the translator’s attention from a lexical item to an item of meaning. It is impossible to
study an expression without its context, and no given translation can be ‘inadequate for the context in question’ – as is often the case with dictionary-based equivalents – because they are all already embedded in their proper textual contexts. Another important feature of corpora is the imperfection of language use. Any collection of real texts will contain typos, passages of bad style in the original or translation, and of course translation solutions that run the gamut from excellent to misleading or simply wrong. A corpus user must find a way to critically judge the solutions proposed by the corpus and evaluate them according to the type and contents of the corpus. This point is especially crucial in translator training.

A monolingual corpus is an equally valuable resource, though usually for different purposes. As monolingual corpora are generally larger and, in some cases, may be considered representative, they are able to offer information about more or less standard language use on the basis of quantitative data. Moreover, a monolingual corpus can be an important source of translation equivalents for specific expressions, technical terms or recent borrowings, naturally requiring different search strategies.

Unlike the dictionary, a concordance leaves it to the user to work out how an expression is used from the data. This typically calls for more in-depth processing than does consulting a dictionary, thereby increasing the probability of learning. In more general terms, by drawing attention to the different ways expressions are typically used and with what frequencies, corpora can make learners more sensitive to issues of phraseology, register and frequency, which are poorly documented by other tools (Aston, 1999).

In the remainder of this paper we give an overview of the possibilities to exploit corpora both in practical translation work and in translation research. We first outline the present state of language resources in Slovenia, focusing on publicly available resources that can be accessed and re-used for a variety of purposes. Then we give examples of corpus exploitation in translation work and in translator training, in the creation of translation-relevant terminological resources and in translation research. The concluding discussion shows that there is still room for a more systematic approach to corpus-based research of translation phenomena, and that the resources we have available at present literally call for such analyses.

2. Overview of Mono- and Multilingual Corpora for Slovene

In fairness to various teams and researchers working on Slovene corpora, it should be noted that this section attempts to include only corpora that can be accessed on the Web and that may be considered a translation resource. We therefore will not be concerned with speech databases and collections that have been assembled with the intention of speech technologies, privately owned mono- and multilingual corpora that have been compiled for the purposes of developing a Machine Translation system, as well as all other text collections that cannot be accessed and are not distributed.

2.1 Monolingual corpora

Among the first Slovene electronic text collections was an online repository of Slovene literature compiled by Miran Hladnik (http://www.ijs.si/lit/leposl.html-l2 [21.11.07]). This digital library was founded in 1995 and is still being updated,
however the literary texts today form part of a much larger corpus project, Nova beseda (http://bos.zrc-sazu.si/a_beseda.html [21.11.07]), at the time of writing containing 202 million words. Nova beseda is being compiled at the Fran Ramovš Institute of Slovene Language, which is part of the Slovene Academy of Sciences and Arts, and is freely available for online querying. The corpus is composed mostly of the Slovene daily newspaper Delo (150 million words), while the rest is taken from the above-mentioned literary collection, the computer monthly Monitor and some other minor text sources.

The interface to Nova beseda is rather simplistic and does not offer many advanced options of corpus querying or processing the hits. The texts of Nova beseda have not undergone any linguistic analysis, hence only word form search is possible, with the wildcard characters * and ?. The corpus does not claim to be balanced or representative in any respect, as it contains a very narrow selection of text sources (see above). However, the user has the possibility of restricting the search to an individually defined subcorpus through an easy-to-use bibliographic taxonomy.

The other large Slovene corpus is FIDAlplus (http://www.fidaplus.net [21.11.07]), a 621-million words reference corpus of Slovene, which was compiled within a government-funded research project launched in 2004. As the main objective of a reference corpus is to be as representative of the language in all its varieties as possible, considerable efforts were invested into building a balanced corpus out of a much larger text collection (Arhar and Gorjanc, 2007).

The corpus was morphosyntactically annotated by Amebis (http://www.amebis.si [21.11.07]), a Slovene language technologies company responsible for most commercially available language tools for Slovene. The annotation includes complex morphosyntactic descriptions, i.e. not just part-of-speech tags but an array of all grammatical categories associated with the word form. Furthermore, to each word form was added its lemma or, in case of morphological homography, lemmas. The corpus can be accessed via a web concordance engine ASP and is free for research purposes upon registration.

2.2 Special language corpora

For terminology work, as well as mono- and multilingual, another corpus type is extremely useful: the domain-specific, special language or sublanguage corpus. For this corpus type it is important that it is representative of the domain in terms of the text types contained and the actuality of the texts. Such a collection can almost never be entirely bilingual, because a special domain is best represented by a collection of crucial texts in one language. Several criteria should be considered when compiling a sublanguage corpus (Pearson 1998: 56):

- Register. A special domain like, say, genetics, will typically be described in texts of various registers, e.g. scientific papers, college textbooks, articles in popular scientific journals etc. Register can have a considerable influence on the terminology used and the style.
- Quality. Although in itself a slippery issue, texts do differ in the amount of effort invested into all stages of their production, from authorship to typesetting and printing. Corpora generally should not impose normative restrictions, however
for domain-specific corpora certain texts might be inappropriate on the grounds of poor quality.

- Original, translated or written in a foreign language. In most scientific domains researchers publish their work in languages other than their own, either as written by themselves or translated into the target language. Such texts should by no means be considered substandard because they too constitute the language reality in a given domain. We should, however, be aware of the characteristics of such texts and possible inconsistencies resulting from them.

Apart from the two large general language corpora for Slovene mentioned above, several projects within the last few years have yielded a set of specialized monolingual corpora. One covers the domain of information science and includes proceedings of the largest Slovene IT conference DSI from 2003 to 2007 (Days of Slovene Information Science). At the time of writing it has 1.2 million words and is available for online querying at http://nl2.ijs.si/index-mono.html [21.11.07] (Erjavec and Vintar, 2004). The domain of Informatics is a highly productive and terminologically challenging one for all non-English languages, and a monitor corpus is the best way to follow language development fuelled by technology. The DSI corpus was compiled as support for Islovar, the interactive online Slovene–English terminological dictionary of Informatics (Islovar, http://www.islovar.org [21.11.07]).

Another such corpus consists of texts from the domain of Public Relations, it contains just under 2 million running words and is available for online search at http://www.korp.fdv.uni-lj.si/ [21.11.07].

### 2.2 Multilingual corpora

As a small language with close contacts with other linguistic communities, Slovene has a high level of translation activity. Accordingly, the need for and appreciation of multilingual resources have fuelled several projects of compiling parallel corpora. The most interesting as well as easiest to obtain is the language pair Slovene–English, which is by now very well served: the total size of freely available Slovene–English parallel corpora amounts to over 35 million words. Other languages lag far behind, with the noble exception of Evrokorpus, now containing a Slovene-German and a Slovene-French part of the corpus.

#### 2.2.1 MULTEXT-East

The name refers to a large initiative, within which a set of corpora and tools were built or made available, covering a large number of mainly Central and Eastern European languages (Erjavec, 2004). The most important component is the linguistically annotated corpus consisting of Orwell's novel *1984* in the English original and translations. The resources are the results of several EU projects: MULTEXT-East (produced linked resources for Romanian, Slovene, Czech, Bulgarian, Estonian, Hungarian and English), TELRI (added resources for Lithuanian, Croatian, Serbian and Russian; first release), and CONCEDE (validation, re-encoding; partial re-release). This dataset, unique in terms of languages and the wealth of encoding, is
extensively documented (http://nl.ijs.si/ME/ [21.11.07]), and freely available for research purposes, upon signing the licence agreement.

2.2.2 IJS-ELAN

The IJS-ELAN Slovene–English parallel corpus includes 15 texts from various domains; the total size of the corpus is 1 million words (Erjavec, 2002). The basic idea behind this project was to build as big a parallel corpus as possible, in the quickest way possible. The already existing MULTEXT-East corpus, consisting of Orwell’s 1984, was expanded through a further 14 texts, ranging from EU legislation and pharmacology to computer manuals and localisation files. As text availability was the main criterion in building this corpus, the selection is quite haphazard. An online concordancer was set up shortly after the texts had been preprocessed and the corpus has since been used for a variety of purposes, including as a translation resource (http://nl2.ijs.si/index-bi.html [21.11.07]).

2.2.3 Trans

The Trans Slovene–English parallel corpus was compiled in a rather unspectacular manner – as a student project at the Department of Translation, University of Ljubljana. It contains 1 million words and was compiled specifically for translation purposes, which meant that the number of domains covered by the texts was deliberately limited to five: medicine, geology, tourism, nuclear engineering and public administration. The corpus was made available for online search at the same address as the IJS-ELAN corpus (see previous section).

2.2.4 Evrokorpus

The largest translation project in Slovenian history was the translation of the aquis communautaire, a prerequisite for accession to the European Union and a foundation for all legal and administrative matters concerning EU. As the majority of translation work was performed by the Office of the Government of the Republic of Slovenia for European Affairs using Translation Memory tools, the resulting databases of bilingual segments could easily be converted into a searchable corpus. The first such collection was made available by Miran Željko in 2002 under the name Evrokorpus (http://evrokorpus.gov.si/ [21.11.07]). The corpus has since grown to an astounding size of 34 million words Slovene-English parallel materials, 1 million Slovene-German and about 200,000 words Slovene-French. It is being regularly updated with new aligned translations and presents an invaluable resource for translators and terminologists, but also legal experts and others working in the EU domain.

The fact that during the process of EU enlargement most texts produced were made publicly available as a parallel corpus is an unprecedented advantage for translators from and into Slovene. Combined with the terminology database Evroterm (http://evroterm.gov.si/ [24.9.06]), this is a unique infrastructure ensuring consistent translations in all EU-related domains (Željko 2004).
3. Corpora in Translation Practice and Translator Training

For a translator, a corpus is one of the sources of linguistic information, either on the lexical level when searching for translation equivalents or on other levels seeking to produce a functional translation. As the primary source of lexical information, most translators still rely on dictionaries, although in special domains term banks may be used much more often than general language dictionaries. If an item is not found in the dictionary, the next stage is usually Google. Clearly the Internet is a gold mine for translators, as it contains up-to-date documents on almost all subjects in almost all the languages of the world (Fletcher, 2004). However, most documents on the Web are not bilingual, and the quest for translation equivalents requires efficient and innovative search strategies.

The Web is in itself a large multilingual corpus, and there are tools available that facilitate its use as a corpus, such as KwicFinder (http://miniappolis.com/KWiCFinder/KWiCFinderHome.html, [21.11.07]). We might say that between these two extremes, dictionaries as static, normalised, structured data and the Web as unstructured, chaotic, abundant data, there are corpora, some that already exist and some we might build ourselves.

3.1 Using existing corpora

A recently performed experiment at the Department of Translation, University of Ljubljana, compared the quality of translations produced by 3rd year students, where half of the group were allowed to use online corpora, but not Google or other web search engines, and the other half were allowed to browse the web but not use corpora. Both groups were allowed to use local or online dictionaries and terminological resources.

Despite the fact that the sample was relatively small - only 25 students participated in the experiment - two interesting tendencies could be observed. The first was that students using corpora on average produced better translations than the non-corpus group, the difference between the groups was almost one full grade (7.45 vs. 8.25). Another observable tendency showed that corpus-users took longer to produce their translations, on average the corpus group was 11 minutes slower than the non-corpus group.

![Figure 3: Translating with or without corpora](image-url)
To put these tentative results into perspective, we should add that the original text was from the domain of EU regulations for fishing, meaning that most reference materials could be found either in Evrokorpus or in the termbank Evroterm. We should by no means generalize the fact that translations from the corpus group were better, since parallel corpora can only aid translators if - and only if - there exists a corpus containing texts relevant to the original we are currently translating.

For first time corpus users it is important to draw attention to some key issues:

1. Corpora are not dictionaries. Texts may contain language usage that does not correspond to what is considered standard or correct.
2. When using non-lemmatised corpora of highly inflectional languages, the search for the base form will return only a small portion of possible hits. The linguistic pattern of the base form may differ from the patterns of inflected forms.
3. Results from a corpus require critical interpretation. Frequency information should be interpreted according to corpus composition.

A monolingual corpus of the mother language will naturally be used for different purposes than a corpus of a foreign language. An interesting feature is the search for translation equivalents in a monolingual corpus. An English word like *spam* will first occur in Slovene as a borrowing, so the search for *spam* in *Nova beseda* returns a considerable number of hits, where, if we examine the context, several possible translation equivalents occur near the borrowed word, e.g. *nezaželena pošta*, *elektronske smeti*, *nenaročena oglasna pošta* etc.

Although we normally think of corpora as synchronic resources portraying language at a certain point in time, some interesting studies into term formation have been made for Slovene and English, for example for the field of mobile communications (Glavan, 2004). The corpus *Nova beseda* was used for diachronic research by building several subcorpora according to the year of publication. In this way the frequency of terms like *mobitel*, *WAP*, *wapanje* etc. could be explored year-wise and the tendencies of terminological development quantified.

### 3.2 Using self-made corpora

For many languages, special domains or language pairs, there are no available corpora. On the other hand, the internet is an infinite source of documents and texts on all possible subjects, some available in two or more languages. In addition, most people are in the habit of storing their translation projects on hard disk, and if there were a systematic way of searching through all these files, the process of retrieving previously used items of information might be much faster and easier.

Arguments in favour of compiling one’s own corpora are many, although to most people the effort seems too strenuous considering the potential benefits. Especially in view of translation memories and the idea of reusability behind them, it seems that bilingual text collections are gaining ground as key resources in translation. Of course, the purpose of these two types of resources differs to a great extent. While translation memories provide reusability only at the rather rigid level of sentence
similarity, (bilingual) corpora provide insight into language or translation solutions on almost any imaginable level.

At the Department of Translation in Ljubljana we have undertaken several student projects of compiling bilingual corpora. Such corpus projects have certain limitations compared to corpora compiled within research projects:

- All tools and methods demonstrated should be available to students inside as well as outside the classroom. The experiment should be completely replicable in any other out-of-the-classroom setting.
- All tools should be free and, if possible, run under Windows.
- Translation students generally cannot program, and all data manipulation must be performed using standard text processing software and non-exotic file formats.

The following sections briefly describe the stages involved in building a corpus and the tools available.

3.2.1 Collecting and pre-processing texts

According to the definition given by Sinclair (1991), a corpus is ‘A collection of naturally occurring language text, chosen to characterize a state or variety of a language.’ The choice of texts should therefore be concerned with the representativeness of a corpus, even if only a small domain is to be represented. Of course, in bilingual corpora it is even more difficult to satisfy this criterion, nevertheless the composition of the corpus should at least be thoroughly discussed. The purpose of this discussion is to clarify issues of corpus size, number of domains included, text types, language(s) and/or language of the original, possible text sources, copyright etc.

Once the project has a set of clearly defined objectives in terms of text collection, some technical questions also need to be resolved. Which file formats can be successfully handled? If the main source of texts will be the internet, HTML will need to be handled; if on the other hand we expect text donors from translation agencies or private entities, MS Word is likely to be the most common format. Which character encoding should be used? Probably Unicode or UTF-8, though older tools might have problems displaying them. Which encoding should be chosen for the entire corpus? If we are building a resource that should be used and distributed as widely as possible, we should probably choose the TEI encoding (Sperberg-McQueen & Burnard, 2002), however without appropriate computational knowledge this standard is not trivial to implement.

3.2.2 Alignment

If we are building a parallel corpus, the texts will need to be sentence aligned. If we can get our hands on a licensed copy of SDL Trados WinAlign, alignment is an easy task. A sentence alignment utility is offered by several other translation memory packages (such as ATRIL’s DVX), as well as by the parallel concordance tool ParaConc (http://www.athel.com/para.html [21.11.07]), obtainable for a relatively modest fee.
Sentence alignment is usually a semi-automatic procedure, where the tool proposes sentence pairs, which must be manually corrected in the event of errors. Most commercial alignment utility can handle various file formats, including HTML, Word or XML files.

3.2.3 Offline concordancing

There are a number of tools available for concordancing at modest prices. A widely known toolkit for monolingual text analyses is Wordsmith Tools by Mike Scott (http://www.lexically.net [21.11.07]). While perfectly adequate even for advanced corpus linguists working with monolingual corpora, it is of very limited use for querying bilingual corpora. For the latter, the above-mentioned ParaConc is a good option.

According to the experience gained, building bilingual corpora in an educational setting is not only a useful exercise and a corpus-awareness-raising activity, but also an undertaking that produces extremely valuable resources for the entire translation community.

4. Conclusions

A few years ago corpora were an unexplored terrain for many practising translators and translation tutors alike. This situation seems to be changing both because translators are required to produce high-quality translations in a shorter time than before and because electronic language resources are more accessible than before. The aim of this contribution has been to present the situation in Slovenia and for the Slovene language, which – with its just under 2 million speakers – counts among the smallest language communities in Europe. Nevertheless, in the field of bilingual freely available language resources, Slovene is considerably well provided for. Not many languages can boast an online parallel corpus of over 34 million words, and corpus-related activities in the context of translator training by now have the status of a well established tradition.

Having corpora available is however only the basis for linguistic research, and in this respect there is plenty of room for future work. In the field of corpus-based translation studies, properties of translated texts have been studies and compared to original text production within a language (Baker 2004). Such studies can yield interesting insights not only into the differences between translated and original texts, but also into the cognitive processes underlying translation. To this day no extensive study of this kind has been made for Slovene, we do however hope that with the availability of Fidaplus, which contains a large portion of translations into Slovene, this gap will have been closed soon.
